1. Introduction and Origin

Yellow.ai is an Indian conversational-AI company that focuses on using Natural Language Processing (NLP), machine learning and artificial intelligence to improve customer and employees interactions. In 2016 in Bengaluru , the company was originally founded as Yellow Messenger. It was later rebranded and renamed as Yellow.ai as it expanded its technology beyond basic chatbots and made themselves more advanced AI-based automation.

The main idea was important but simple. The large organizations had a significant number of questions which were repetitive out of the thousands of customer queries that they get everyday. Yellow.ai aimed to solve the problem of manually handling the questions which requires a lot of time, money and human resources by developing AI systems that could easily understand what customers were asking and automatically provide relevant responses.

A noteworthy feature of Yellow.ai is its emphasis on multilingual communication. Since there are hundreds of languages and dialects in India, conversational systems which function only in English would not be adequate for a large number of Indian businesses. That is why Yellow.ai created facilities for languages including Hindi, Tamil, Telugu, Bengali and Marathi, as well as English and a number of foreign languages. This ability to support multiple languages became one of the key features that enabled the company to differentiate itself in the conversational-AI sector.

At first the company placed a greater emphasis on automation based on chatbots but later moved on to include areas such as voice bots, generative AI and autonomous AI agents. Its technology is currently being used by businesses all over the world for customer support, employee assistance, sales and other business processes.

Yellow.ai has secured approximately $102 million in funding as a result of several funding rounds; one of its key achievements was the $78 million Series C funding round in 2021, which was headed by WestBridge Capital and also involved investors such as Sapphire Ventures, Salesforce Ventures and Lightspeed Venture Partners.

The fact that the company has expanded internationally and has a presence in the United States means that Bengaluru remains an important centre for engineering and technology work at Yellow.ai; this is in keeping with a typical situation among Indian technology start-ups, namely that they may operate on a global scale while at the same time keeping a major portion of their technical development in India..

2. Founder Details

Yellow.ai was set up by Raghu Ravinutala, Jaya Kishore Reddy Gollareddy and Rashid Khan, with Raghu Ravinutala serving as the company's co-founder and CEO and having played a significant part in developing its general vision and in its growth. He has on many occasions commented on the way that conversational AI has evolved from traditional rule-based chatbots to generative AI and autonomous agents.

Jaya Kishore Reddy Gollareddy, who is also one of the co-founders, has been closely linked with the company's work in technology and engineering, and Rashid Khan, who too is one of the original co-founders, took part in shaping the company's technology and product direction.

The founders had strong technical backgrounds; Ravinutala and Gollareddy had left their careers in corporate America in order to pursue their own start-up idea, and Rashid Khan joined the founding team after the company had met him at a college hackathon. It is an interesting aspect of Yellow.ai's history in that it illustrates how technical skills, entrepreneurship and networking can all combine to set up a start-up.

Yellow.ai was also included in programmes such as Microsoft's start-up accelerator and SAP Startup Studio in its early days. The company was able to obtain access to enterprise customers, technological resources and the wider start-up ecosystem as a result of these opportunities.

Instead of treating NLP technology as merely an academic research project, the founders focused on addressing actual business problems. The aim was to make conversational AI useful to real companies that needed to automate large numbers of customer interactions..

3. Products and Services

Yellow.ai's primary product is its enterprise conversational-AI platform, a platform currently linked with YellowG and its generative-AI features. It enables organisations to develop AI-powered chatbots, voice bots and AI agents which are capable of interacting with both customers and employees.

The following discussion covers some of the key technologies and features provided by the platform.

DynamicNLP:

DynamicNLP is the natural language processing technology that is proprietary to Yellow.ai; it enables the system to understand messages sent by users and to determine the intention behind them. Rather than asking each organisation to create an NLP model from scratch, the platform offers pre-trained features which can be tailored to meet various business needs.

For instance, when a customer types something such as "I haven't received my refund yet", the system has to recognise that the customer is inquiring about the status of a refund and not just look for a match with individual words. This ability to understand intent is an important application of NLP.

YellowG and Multi-LLM Orchestration:

Yellow.ai has likewise pursued a move into generative AI via YellowG; the platform is able to work with a number of large language models rather than relying entirely on a single particular model.

It is advantageous for businesses since various LLMs may differ in terms of accuracy, speed, and cost. By using multi-LLM orchestration, companies can choose or direct their requests to the appropriate models based on their needs.

Generative-AI-Powered Inbox:

A further feature is the Inbox powered by AI, which is intended to aid human customer-service agents. It is not necessary or appropriate for an AI system to deal with every customer query. In these cases, the AI can help a human agent by suggesting possible responses, supplying information and assisting in the quicker resolution of queries.

What this results in is a mix of AI automation and human involvement, rather than viewing AI as a full substitute for human employees.

Zero-Setup Deployment and Templates:

Yellow.ai also includes ready-made conversational templates and solutions that are specific to various industries, such as banking, retail, manufacturing, travel and e-commerce.

The purpose of these templates is to cut down the time needed to develop a conversational AI application; rather than beginning with a blank system, an organisation can start with a framework that is already available and then alter it to meet its own requirements.

Omnichannel Support:

A major feature of Yellow.ai is its capability to deploy conversational agents on a number of different communication channels, such as WhatsApp, websites, voice and IVR systems, Instagram, Facebook Messenger, Slack and Microsoft Teams, and others.

Besides its primary software platform, Yellow.ai obtains revenue from enterprise implementations, partnerships and other services such as analytics and voice automation. This is in keeping with the standard enterprise Software-as-a-Service (SaaS) model, under which organisations pay for access to the platform and for additional features depending on their needs

4. Customers Catered To

Yellow.ai primarily focuses on enterprise customers rather than individual consumers. Its platform is used by organisations across industries such as aviation, retail, hospitality, logistics, automotive, banking and telecommunications.

The company has reported serving more than 1,000 organisations across around 85 countries. This international presence is important because conversational AI has to deal with very different languages, cultures and communication styles depending on the market.

One example is AirAsia, where Yellow.ai's technology has been used to help employees access internal information and policies more quickly. AI-based systems can reduce the time employees spend searching through large amounts of information and allow them to focus more on their actual work.

Another example is Lulu Hypermarket, where conversational AI has been used for customer-support interactions. The platform has helped handle a large number of customer queries, which would otherwise require considerable human effort.

Yellow.ai has also worked with Lion Parcel, an Indonesian logistics company. According to reported case-study results, the company's AI-based bots achieved a high level of automation for shipping-related enquiries across channels such as WhatsApp, Facebook and Instagram.

Other companies associated with Yellow.ai include Sony, Domino's, Sephora, Hyundai, Skoda Auto, Volkswagen, Papa John's, OYO, ITC Limited and Randstad. These organisations operate in very different sectors, which demonstrates the flexibility of conversational-AI technology.

Overall, Yellow.ai's customer base shows that NLP is no longer limited to research laboratories or simple chatbots. It is increasingly being used as a practical business technology. By combining NLP with machine learning, generative AI, voice technology and multilingual support, Yellow.ai has developed its platform to handle real-world communication at a large scale.

From an NLP perspective, Yellow.ai is particularly interesting because its products demonstrate how concepts such as intent detection, language understanding, multilingual NLP, conversational context, large language models and automated response generation can be converted into commercial applications. Its growth also shows how NLP has moved from being mainly a research area to becoming an important part of modern enterprise software.

Yellow.ai has its target set on large businesses rather than individuals. Its system has been embraced by organisations from industries like aviation, retail, hospitality, logistics, automobile, finance and telecoms.

The organisation reports that presently, they have been working with more than 1000 clients from about 85 countries. This is significant as conversational AI has to address the issue of language, culture and communication norms depending on the market.

One of the major indicative customers is AirAsia that uses Yellow.ai's technology to allow employees to find internal rules and regulations in a faster way. AI solutions help save employees time that they spend on searching massive databases instead of performing their duties.

Another example is Lulu Hypermarket where the conversational AI helped manage customer-support communications. It solved the problems of a massive number of customer inquiries which otherwise would have required a lot of human efforts.

Yellow.ai also provided its services to Lion Parcel, an Indonesian company focused on logistics. According to the case description, the company was able to provide a high level of automation of shipment inquiries via channels like WhatsApp, Facebook and Instagram.

The companies connected with Yellow.ai are Sony, Domino's, Sephora, Hyundai, Skoda Auto, Volkswagen, Papa John's, OYO, ITC Limited, and Randstad. These companies work in different sectors, which shows the versatility of conversational AI technology.

All in all, Yellow.ai's customers indicate that NLP is no longer limited to research laboratories or simple chatbots, but rather is becoming a beneficial technology for business purposes.

Combining NLP with machine learning, generative AI, voice technology, and multilingualism is what allows Yellow.ai to implement its platform.

From an NLP point of view, Yellow.ai is very interesting because its products illustrate the use of such concepts as intention detection, language comprehension, multilingual NLP, conversational context, large language models, and automation of responses for commercial purposes..

5. Tools, Technology Stack and Innovation

One of the advantages of Yellow.ai is based upon the number of key points. Firstly, the company states that its NLP engine is pre-trained and capable of self-improvement, when compared to other vendors, it gives the same accuracy by maintaining about half the amount of training data, and therefore reducing the time it takes for an enterprise to go live with a new bot.

Secondly, Yellow.ai changed from having only rule-based and intent-based bots to using large-language-model-supported generative agents—something that has been rapidly increased up since 2022— rather than relying on scripted decision trees, it is allowed to provide dynamic and context-sensitive responses, while at the same time allowing enterprises to put constraints on the outputs for regulated sectors such as banking and insurance.

Third, instead of depending on one foundation model, the company's multi-LLM orchestration layer is itself a notable piece of engineering, Yellow.ai built infrastructure to plug in and switch between more than fifteen LLMs, optimising each conversation for the right balance of cost, speed and quality.

Fourth, deep multilingual coverage of Indian and Southeast Asian languages, built on top of the company's original DynamicNLP research, it protects the market position from global competitors like Intercom Finn, Botpress, and Voice Flow, which have historically concentrated on English-first markets. In 2025 and 2026 the company has been transferring its entire platform around autonomous AI agents rather than the older "conversational AI" framing, giving back the wider industry change from single-turn chatbots toward agents capable of completing multi-step tasks with minimal human supervision.

6. Revenue and Scale

Yellow.ai's annual recurring revenue is estimated to be almost 80 million US dollars, which is approximately equal to several hundred crore rupees and therefore above the five-crore-per-annum figure that distinguishes a revenue-producing NLP start-up from one that is still in an early pilot stage.

During the company's period of fastest expansion, it achieved year-on-year recurring revenue growth of more than 400%, and within two years of setting up, it reached its $1 million of annual recurring revenue — a good quick progression for an enterprise SaaS company based on natural language technology. Its most recent valuation, after the 2021 Series C financing, is estimated to be about 500 million US dollars, and as of early 2026 it has more than 875 employees worldwide, with important changes to its workforce made in late 2025 as part of its strategic move towards AI-agent products.

7. Conclusion

Yellow.ai shows the path by which an NLP company founded in India can develop from a project started during a college hackathon into a globally distributed, enterprise-level AI platform that earns tens of millions of dollars in recurring revenue.

The company's development reflects the general evolution of the NLP industry: it began with rule-based, intent-driven chatbots, then added proprietary pre-trained language models in order to lessen the enterprise burden of training NLP systems, and finally adopted large language models and multi-agent orchestration as generative AI has developed.

Yellow.ai is a useful case study for a course in Natural Language Processing and Computational Linguistics because of its core intellectual property — DynamicNLP, its multilingual intent models and its LLM-routing layer — is exactly at the point where applied linguistics, machine learning engineering and enterprise product design come together.
